THE $\mathfrak{sl}_3$ SELBERG INTEGRAL

S. OLE WARNAAR

Abstract. Using an extension of the well-known evaluation symmetry, a new Cauchy-type identity for Macdonald polynomials is proved. After taking the classical limit this yields a new $\mathfrak{sl}_3$ generalisation of the famous Selberg integral. Closely related results obtained in this paper are an $\mathfrak{sl}_3$-analogue of the Askey–Habsieger–Kadell $q$-Selberg integral and an extension of the $q$-Selberg integral to a transformation between $q$-integrals of different dimensions.

1. Introduction

Let $\mathfrak{g}$ be a simple Lie algebra of rank $n$, with simple roots, fundamental weights and Chevalley generators given by $\alpha_i$, $\Lambda_i$ and $e_i, f_i, h_i$ for $1 \leq i \leq n$. The roots of $\mathfrak{g}$ are normalised such that the maximal root $\theta$ has length $\sqrt{2}$, i.e., $(\theta, \theta) = 2$, where $(\cdot, \cdot)$ is the standard bilinear symmetric form on the dual of the Cartan subalgebra.

Let $V_\lambda$ and $V_\mu$ be highest weight modules of $\mathfrak{g}$ with highest weights $\lambda$ and $\mu$, and denote by $\text{Sing}_{\lambda, \mu}[\nu]$ the space of singular vectors of weight $\nu$ in $V_\lambda \otimes V_\mu$:

$$\text{Sing}_{\lambda, \mu}[\nu] = \{ v \in V_\lambda \otimes V_\mu : h_i v = \nu(h_i) v, \ e_i v = 0, \ 1 \leq i \leq n \}.$$ 

For fixed nonnegative integers $k_1, \ldots, k_n$ assign $k := k_1 + \cdots + k_n$ integration variables $t_1, \ldots, t_k$ to $\mathfrak{g}$ by attaching the $k_i$ variables

$$t_1 + k_1 + \cdots + k_{i-1}, \ldots, t_{k_i} + \cdots + k_i$$

to the simple root $\alpha_i$. In other words, the first $k_1$ integration variables are attached to $\alpha_1$, the second $k_2$ to $\alpha_2$ and so on. By a mild abuse of notation, also set

$$\alpha_{t_j} = \alpha_i \quad \text{if} \quad k_1 + \cdots + k_{i-1} < j \leq k_1 + \cdots + k_i.$$ 

Exploiting the connection between Knizhnik–Zamolodchikov equations and hypergeometric integrals, see e.g., [3, 22, 26], Mukhin and Varchenko [20] conjectured in 2000 that if the space

$$\text{Sing}_{\lambda, \mu}[\lambda + \mu - \sum_{i=1}^n k_i \alpha_i]$$

is one-dimensional, then there exists a real integration domain $\Gamma$ such that a closed-form evaluation exists (in terms of products of ratios of Gamma functions) for the $\mathfrak{g}$ Selberg integral

$$\int_{\Gamma} \left[ \prod_{i=1}^k \frac{t_i^{-(\lambda, \alpha_i)} (1 - t_i)^{-(\mu, \alpha_i)}}{\prod_{1 \leq i < j \leq k} |t_i - t_j|^{(\alpha_i, \alpha_j)}} \right]^\gamma \ dt_1 \cdots dt_k.$$

For \( g = \mathfrak{s}l_3 \) the evaluation of (1.1) is well-known and corresponds to the celebrated Selberg integral \(^{23,18,4}\):

\[
2 S. OLE WARNAAR
\]

\[
\begin{aligned}
(1.2) \quad & \int_{0 < t_1 < \ldots < t_k < 1} \prod_{i=1}^{k} t_i^{\beta_i - 1} (1 - t_i) \prod_{1 \leq i < j \leq k} |t_i - t_j|^{2\gamma} \, dt_1 \cdots dt_k \\
& = \prod_{i=0}^{k-1} \frac{\Gamma(\alpha + i\gamma)\Gamma(\beta + i\gamma)\Gamma((i + 1)\gamma)}{\Gamma(\alpha + \beta + (i + k - 1)\gamma)\Gamma(\gamma)},
\end{aligned}
\]

where \( \Re(\alpha) > 0, \Re(\beta) > 0, \Re(\gamma) > -\min\{1/k, \Re(\alpha)/(k - 1), \Re(\beta)/(k - 1)\} \).

The prospect that generalisations of this extremely important integral exist for all simple Lie algebras has led to much recent progress in evaluating hypergeometric integrals, see e.g., \([4,8,19,25,27,29,30,31]\).

In \([23]\) Tarasov and Varchenko obtained an evaluation of (1.1) for \( g = \mathfrak{s}l_3, \lambda = \lambda_1 \Lambda_1 + \lambda_2 \Lambda_2, \mu = \mu_2 \Lambda_2 \) and \( k_1 \leq k_2 \) as follows.

**Theorem 1.1** (Tarasov–Varchenko). For \( 0 \leq k_1 \leq k_2 \) let \( t = (t_1, \ldots, t_{k_1}), s = (s_1, \ldots, s_{k_2}) \), and let \( \alpha_1, \alpha_2, \beta_2, \gamma \in \mathbb{C} \) such that \( \Re(\alpha_1), \Re(\alpha_2), \Re(\beta_2) > 0 \) and \( |\gamma| \) is sufficiently small. Then

\[
(1.3) \quad \int \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} C_{\gamma}^{k_1,k_2}[0,1] \frac{k_1}{k_2} \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} |t_i - s_j|^{2\gamma} \, dt \, ds
\]

\[
= \prod_{i=0}^{k_1-1} \frac{\Gamma(\alpha_1 + i\gamma)\Gamma(1 + (i - k_2)\gamma)\Gamma((i + 1)\gamma)}{\Gamma(\alpha_1 + 1 + (i + k_1 - k_2 - 1)\gamma)\Gamma(\gamma)}
\]

\[
\times \prod_{i=0}^{k_2-1} \frac{\Gamma(\alpha_2 + i\gamma)\Gamma(\beta_2 + i\gamma)\Gamma((i + 1)\gamma)}{\Gamma(\alpha_2 + \beta_2 + (i + k_2 - k_1 - 1)\gamma)\Gamma(\gamma)}
\]

\[
\times \prod_{i=0}^{k_1-1} \frac{\Gamma(\alpha_1 + \alpha_2 + (i - 1)\gamma)}{\Gamma(\alpha_1 + \alpha_2 + \beta_2 + (i + k_2 - 2)\gamma)}
\]

\[
\times \prod_{i=0}^{k_1-1} \frac{\Gamma(\alpha_2 + \beta_2 + (i + k_2 - k_1 - 1)\gamma)}{\Gamma(\alpha_2 + (i + k_2 - k_1)\gamma)},
\]

where \( dt = dt_1 \cdots dt_{k_1} \) and \( ds = ds_1 \cdots ds_{k_2} \).

In the above, \( C_{\gamma}^{k_1,k_2}[0,1] \) is a somewhat complicated integration chain defined in \((3.8)\) on page \([16]\). Since

\[
C_{\gamma}^{0,k}[0,1] = \{(s_1, \ldots, s_k) \in \mathbb{R}^k : 0 < s_1 < \cdots < s_k < 1\}
\]

the Tarasov–Varchenko integral simplifies to the Selberg integral when \( (k_1, k_2) = (0, k) \).

In \([29,31]\) the present author developed a method for proving Selberg-type integrals using Macdonald polynomials. This resulted in an evaluation of (1.1) for
\[ g = \mathfrak{sl}_n \text{ where } \lambda = \sum \lambda_i A_i, \quad \mu = \mu_n A_n \text{ and } k_1 \leq k_2 \leq \cdots \leq k_n, \] generalising the Selberg and Tarasov–Varchenko integrals. In this paper we again employ the theory of Macdonald polynomials to establish the following Cauchy-type identity. For \( \lambda \) and \( \mu \) partitions (and not, as above, weights of \( g \)) let \( P_\lambda \) be a suitably normalised Macdonald polynomial. Furthermore, let \( (a)_n \) be a \( q \)-shifted factorial and \( (a)_\lambda \) a generalised \( q \)-shifted factorial. (For precise definitions of all of the above, see Section 2.1.)

**Theorem 1.2.** Let \( X = \{x_1, \ldots, x_n\} \) and \( Y = \{y_1, \ldots, y_m\} \). Then

\[
\sum_{\lambda, \mu} |\lambda|^{-n|\mu|} P_\lambda(X) P_\mu(Y) \left( at^{m-1}\lambda(qt^n/a)_\mu \prod_{i=1}^m \prod_{j=1}^m \left( at^{-i-1}\lambda - \mu_j \right) \right)
\]

\[
= \prod_{i=1}^n (ax_i)_\infty \prod_{j=1}^m (qy_j/a)_\infty \prod_{i=1}^n \prod_{j=1}^m (tx_iy_j)_\infty.
\]

For \( m = 0 (n = 0) \) the above identity reduces to the \( q \)-binomial theorem for Macdonald polynomials in \( X(X) \). Theorem 1.2 may thus be viewed as two coupled, multidimensional \( q \)-binomial theorems. In the special case \( (X, Y, a, q, t) \mapsto (X/q, qY, -q^2, q^2, q^2) \) the theorem simplifies to Kawanaka’s \( q \)-Cauchy identity for Schur functions [13] (with the proviso that Kawanaka’s description of the summand is significantly more involved).

After a limiting procedure, which turns the sums over \( \lambda \) and \( \mu \) into integrals, Theorem 1.2 becomes a new evaluation of the Selberg integral (1.1) for \( g = \mathfrak{sl}_3 \) as follows.

**Theorem 1.3.** Let \( t = (t_1, \ldots, t_k) \), \( s = (s_1, \ldots, s_k) \) and let \( \alpha_1, \alpha_2, \beta_1, \beta_2, \gamma \in \mathbb{C} \) such that \( \text{Re}(\alpha_1), \text{Re}(\alpha_2), \text{Re}(\beta_1), \text{Re}(\beta_2) > 0, |\gamma| \) is sufficiently small,

\[
\beta_1 + (i - k_2 - 1)\gamma \notin \mathbb{Z} \quad \text{for } 1 \leq i \leq \min\{k_1, k_2\}
\]

and

\[
\beta_1 + \beta_2 = \gamma + 1.
\]

Then

\[
\int_{C_{\beta_1, \gamma}^{k_1, k_2} [0, 1]} \prod_{i=1}^{k_1} t_i^{\alpha_1 - 1}(1 - t_i)^{\beta_1 - 1} \prod_{i=1}^{k_2} s_i^{\alpha_2 - 1}(1 - s_i)^{\beta_2 - 1}
\]

\[
\times \prod_{1 \leq i < j \leq k_1} |t_i - t_j|^{2\gamma} \prod_{1 \leq i < j \leq k_2} |s_i - s_j|^{2\gamma} \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} |t_i - s_j|^{-\gamma} \ dt \ ds
\]

\[
= \prod_{i=0}^{k_1 - 1} \frac{\Gamma(\alpha_i + i\gamma)\Gamma(\beta_1 + (i - k_2)\gamma)\Gamma((i + 1)\gamma)}{\Gamma(\alpha_1 + (i + k_1 - k_2 - 1)\gamma)\Gamma(\gamma)}
\]

\[
\times \prod_{i=0}^{k_2 - 1} \frac{\Gamma(\alpha_2 + i\gamma)\Gamma(\beta_2 + (i)\gamma)\Gamma((i + 1)\gamma)}{\Gamma(\alpha_2 + \beta_2 + (i + k_2 - k_1 - 1)\gamma)\Gamma(\gamma)}
\]

\[
\times \prod_{i=0}^{k_1 - 1} \frac{\Gamma(\alpha_1 + \alpha_2 + (i - 1)\gamma)}{\Gamma(\alpha_1 + \alpha_2 + (i + k_2 - 1)\gamma)}.
\]
where \( dt = dt_1 \cdots dt_k, \) \( ds = ds_1 \cdots ds_k \) and \( C_{\beta, \gamma}^{k_1, k_2}[0, 1] \) the integration chain defined in (3.5) on page 17.

Since
\[
C_{\beta, \gamma}^{k_0, 0}[0, 1] = \{(t_1, \ldots, t_k) \in \mathbb{R}^k : 0 < t_1 < \cdots < t_k < 1\},
\]
the integral (1.4) again contains the Selberg integral (1.2) as special case. Unlike (1.5), however, (1.4) exhibits \( \mathbb{Z}_2 \) symmetry thanks to
\[
(1.5) \quad C_{\beta, \gamma}^{k_2, k_1}[0, 1] = C_{\beta, \gamma}^{k_1, k_2}[0, 1] \prod_{i=0}^{k_1-1} \Gamma(\beta_1 + i\gamma) \prod_{i=0}^{k_2-1} \Gamma(\beta_2 + (i-k_2)\gamma) \prod_{i=0}^{k_2-1} \Gamma(\beta_2 + i\gamma)
\]
for \( \beta_1 + \beta_2 = \gamma + 1 \), and
\[
\prod_{i=0}^{k_1-1} \Gamma(\alpha_1 + \alpha_2 + (i-1)\gamma) \prod_{i=0}^{k_2-1} \Gamma(\alpha_1 + \alpha_2 + (i-1+k_1-1)\gamma)
\]

If we specialise \( \beta_2 = \gamma \) in (1.3) and \( (\beta_1, \beta_2) = (1, \gamma) \) in (1.4) then the respective products over gamma functions on the right coincide. Since also
\[
(1.6) \quad C_{\gamma}^{k_1, k_2}[0, 1] = C_{\gamma}^{k_2, k_1}[0, 1]
\]
(see Section 3.1 for more details) the two \( \mathfrak{sl}_3 \) integrals are indeed identical for this particular specialisation.

## 2. Macdonald Polynomials

### 2.1. Definitions and notation

Let \( \lambda = (\lambda_1, \lambda_2, \ldots) \) be a partition, i.e., \( \lambda_1 \geq \lambda_2 \geq \ldots \) with finitely many \( \lambda_i \) unequal to zero. The length and weight of \( \lambda \), denoted by \( l(\lambda) \) and \( |\lambda| \), are the number and sum of the nonzero \( \lambda_i \), respectively.

Two partitions that differ only in their string of zeros are identified, and the unique partition of length (and weight) 0 is itself denoted by 0. The multiplicity of the part \( i \) in the partition \( \lambda \) is denoted by \( m_i = m_i(\lambda) \), and occasionally we will write \( \lambda = (1^m_1, 2^m_2, \ldots) \).

We identify a partition with its diagram or Ferrers graph, defined by the set of points in \( (i, j) \in \mathbb{Z}^2 \) such that \( 1 \leq j \leq \lambda_i \). The conjugate \( \lambda' \) of \( \lambda \) is the partition obtained by reflecting the diagram of \( \lambda \) in the main diagonal, so that, in particular, \( m_i(\lambda) = \lambda_i' - \lambda_i' + 1 \). The statistic \( n(\lambda) \) is given by
\[
n(\lambda) = \sum_{i \geq 1} (i-1)\lambda_i = \sum_{i \geq 1} \left( \frac{\lambda_i'}{2} \right).
\]

The dominance partial order on the set of partitions of \( \mathbb{N} \) is defined by \( \lambda \geq \mu \) if \( \lambda_1 + \cdots + \lambda_i \geq \mu_1 + \cdots + \mu_i \) for all \( i \geq 1 \). If \( \lambda \geq \mu \) and \( \lambda \neq \mu \) then \( \lambda > \mu \).

If \( \lambda \) and \( \mu \) are partitions then \( \mu \leq \lambda \) if (the diagram of) \( \mu \) is contained in (the diagram of) \( \lambda \), i.e., \( \mu_i \leq \lambda_i \) for all \( i \geq 1 \).

For \( s = (i, j) \in \lambda \) the integers \( a(s), a'(s), l(s) \) and \( l'(s) \), known as the arm-length, arm-colength, leg-length and leg-colength of \( s \), are defined as
\[
a(s) = \lambda_i - j, \quad a'(s) = j - 1, \\
l(s) = \lambda_j' - i, \quad l'(s) = i - 1.
\]
Note that \( n(\lambda) = \sum_{s \in \lambda} l(s) \). Using the above we define the generalised hook-length polynomials \( c_\lambda \) and \( c'_\lambda \) as

\[
c_\lambda = c_\lambda(q, t) := \prod_{s \in \lambda} (1 - q^{a(s)}t^{l(s)+1}),
\]

\[
c'_\lambda = c'_\lambda(q, t) := \prod_{s \in \lambda} (1 - q^{a(s)+1}t^{l(s)}).
\]

The ordinary \( q \)-shifted factorial are given by

\[
(a)_\infty = (a; q)_\infty := \prod_{i=0}^\infty (1 - aq^i)
\]

and

\[
(b)_z = (a; q)_z := \frac{(b)_\infty}{(aq^z)_\infty}.
\]

Note in particular that for \( N \) a positive integer \( (b)_N = (1-b)(1-bq)\cdots(1-bq^{N-1}) \), and \( 1/(q)_-N = 0 \). Also note that \( c'_\lambda(q^k) = (q)_\lambda \). The \( q \)-shifted factorials can be generalised to allow for a partition as indexing set:

\[
(b)_\lambda = (b; q, t)_\lambda := \prod_{s \in \lambda} (1 - bq^{a(s)}t^{-l'(s)}) = \prod_{i=1}^{l(\lambda)} (bq^{1-i})_{\lambda_i}.
\]

With this notation,

\[
(2.1a)
\]

\[
c_\lambda = (t^n)_\lambda \prod_{1 \leq i < j \leq n} \frac{(t^{j-i})_{\lambda_i - \lambda_j}}{(t^{j-i+1})_{\lambda_i - \lambda_j}},
\]

\[
(2.1b)
\]

\[
c'_\lambda = (qt^{n-1})_\lambda \prod_{1 \leq i < j \leq n} \frac{(qt^{j-i-1})_{\lambda_i - \lambda_j}}{(qt^{j-i})_{\lambda_i - \lambda_j}},
\]

where \( n \) is an arbitrary integer such that \( n \geq l(\lambda) \). We also introduce the usual condensed notation

\[
(a_1, \ldots, a_k)_N = (a_1)_N \cdots (a_k)_N
\]

and likewise for \( q \)-shifted factorials indexed by partitions.

2.2. Macdonald polynomials. Let \( S_n \) denote the symmetric group, and \( \Lambda_n = \mathbb{Z}[x_1, \ldots, x_n]^{S_n} \) the ring of symmetric polynomials in \( n \) independent variables.

For \( X = \{x_1, \ldots, x_n\} \) and \( \lambda = (\lambda_1, \ldots, \lambda_n) \) a partition of length at most \( n \) the monomial symmetric function \( m_\lambda(X) \) is defined as

\[
m_\lambda(X) = \sum_{\alpha} x_1^{\alpha_1} \cdots x_n^{\alpha_n},
\]

where the sum is over all distinct permutations \( \alpha = (\alpha_1, \ldots, \alpha_n) \) of \( \lambda \). If \( l(\lambda) > n \) then \( m_\lambda(X) := 0 \). The monomial symmetric functions \( m_\lambda(X) \) for \( l(\lambda) \leq n \) form a \( \mathbb{Z} \)-basis of \( \Lambda_n \).

A \( \mathbb{Q} \)-basis of \( \Lambda_n \) is given by the power-sum symmetric functions \( p_\lambda(X) \), defined as

\[
p_r(X) = \sum_{i=1}^n x_i^r
\]

for \( r \geq 0 \) and \( p_\lambda(X) = p_{\lambda_1}(X) \cdots p_{\lambda_n}(X) \). The power-sum symmetric functions may be used to define an extremely powerful notational tool in symmetric-function
theory, known as plethystic or $\lambda$-ring notation, see [7, 14]. First we define the plethystic bracket by

$$f[x_1 + \cdots + x_n] = f(x_1, \ldots, x_n)$$

where $f$ is a symmetric function. More simply we just write

$$f[X] = f(X)$$

where on the left we assume the additive notation for sets (or alphabets), i.e., $X = x_1 + \cdots + x_n$ and on the right the more conventional $X = \{x_1, \ldots, x_n\}$. With this notation $f[X + Y]$ takes on the obvious meaning of the symmetric function $f$ acting on the disjoint union of the alphabets $X$ and $Y$. Plethystic notation also allows for the definition of symmetric functions acting on differences $X - Y$ of alphabets, or for symmetric functions acting on such alphabets as $(X - Y)$ allows for the definition of symmetric functions acting on differences $X - Y$ of alphabets, see e.g., [14]. In this paper we repeatedly need this last alphabet when both $X$ and $Y$ contain a single letter, say $a$ and $b$, respectively. We may then take as definition

$$p_r \left[ \frac{a - b}{1 - t} \right] = \frac{a^r - b^r}{1 - t^r},$$

and extend this by linearity to any symmetric function. Note in particular that

$$f \left[ \frac{1 - t^n}{1 - t} \right] = f(t^{n-1}, \ldots, t, 1) =: f((0))$$

corresponds to the so-called principal specialisation, where more generally,

$$\langle \lambda \rangle = \langle \lambda \rangle_n := (q^{\lambda_1}t^{n-1}, q^{\lambda_2}t^{n-2}, \ldots, q^{\lambda_n}t^0),$$

for $l(\lambda) \leq n$.

After this digression we turn to the definition of the Macdonald polynomials and to some of its basic properties [15, 16]. First we define the scalar product $\langle \cdot, \cdot \rangle$ on symmetric functions by

$$\langle p_{\lambda}, p_{\mu} \rangle = \delta_{\lambda\mu} z_{\lambda} \prod_{i=1}^{n} \frac{1 - q^{\lambda_i}}{1 - t^{\lambda_i}},$$

where $z_{\lambda} = \prod_{i \geq 1} m_{i!} i^{m_i}$ and $m_i = m_i(\lambda)$. If we denote the ring of symmetric functions in $n$ variables over the field $\mathbb{F} = \mathbb{Q}(q, t)$ of rational functions in $q$ and $t$ by $\Lambda_{n, \mathbb{F}}$, then the Macdonald polynomial $P_{\lambda}(X) = P_{\lambda}(X; q, t)$ is the unique symmetric polynomial in $\Lambda_{n, \mathbb{F}}$ such that:

$$P_{\lambda}(X) = m_{\lambda}(X) + \sum_{\mu < \lambda} u_{\lambda\mu} m_{\mu}(X)$$

(where $u_{\lambda\mu} = u_{\lambda\mu}(q, t)$) and

$$\langle P_{\lambda}, P_{\mu} \rangle = 0 \quad \text{if} \quad \lambda \neq \mu.$$
This last result may equivalently be stated as the Cauchy identity
\[ \sum_{\lambda} P_\lambda(X)Q_\lambda(Y) = \prod_{i,j=1}^{n} \frac{(txiy_j)_{\infty}}{(x_iy_j)_{\infty}}. \]

We also need the skew Macdonald polynomials \( P_{\lambda/\mu}(X) \) and \( Q_{\lambda/\mu}(X) \) given by
\begin{align*}
P_{\lambda}(X + Y) &= \sum_{\lambda} P_{\lambda/\mu}[X]P_{\mu}[Y] \\
Q_{\lambda}(X + Y) &= \sum_{\lambda} Q_{\lambda/\mu}[X]Q_{\mu}[Y],
\end{align*}
so that \( P_{\lambda/0}(X) = P_\lambda(X) \) and \( Q_{\lambda/\mu}(X) = b_\lambda b_\mu^{-1} P_{\lambda/\mu}(X) \). Equivalently,
\[ Q_{\lambda/\mu}(X) = \sum_{\nu} f_{\mu\nu}^\lambda Q_\nu(X), \]
where \( f_{\mu\nu}^\lambda = f_{\mu\nu}^\lambda \) are the \( q,t \)-Littlewood–Richardson coefficients:
\begin{align*}
P_{\mu}(X)P_{\nu}(X) &= \sum_{\lambda} f_{\mu\nu}^\lambda P_\lambda(X).
\end{align*}

From the homogeneity of the Macdonald polynomial it immediately follows that
\[ f_{\mu\nu}^\lambda (q,t) = 0 \text{ if } |\lambda| \neq |\mu| + |\nu|. \]
It may also be shown that \( f_{\mu\nu}^\lambda (q,t) = 0 \) if \( \mu, \nu \not\subseteq \lambda \), so that \( P_{\lambda/\mu}(X) \) vanishes if \( \mu \not\subseteq \lambda \).

To conclude this section we introduce normalisations of the Macdonald polynomials convenient for dealing with basic hypergeometric series with Macdonald polynomial argument:
\begin{align*}
P_{\lambda/\mu}(X) &= t^{n(\lambda) - n(\mu)} \frac{\epsilon_{\mu}^\lambda}{\epsilon_{\lambda}} P_{\lambda/\mu}(X) \\
Q_{\lambda/\mu}(X) &= t^{n(\mu) - n(\nu)} \frac{\epsilon_{\mu}^\lambda}{\epsilon_{\nu}^\mu} Q_{\lambda/\mu}(X).
\end{align*}

Note that
\[ Q_{\lambda/\mu}(X) = t^{2n(\mu) - 2n(\lambda)} \frac{\epsilon_{\lambda}^\mu}{\epsilon_{\mu}^\nu} P_{\lambda/\mu}(X). \]
If we also normalise the \( q,t \)-Littlewood–Richardson coefficients as
\[ f_{\mu\nu}^\lambda = t^{n(\mu) + n(\nu) - n(\lambda)} \frac{\epsilon_{\mu}^\lambda}{\epsilon_{\mu}^\nu} f_{\mu\nu}^\lambda, \]
then all of the preceding formulae have perfect analogues:
\begin{align*}
P_{\lambda}(X + Y) &= \sum_{\mu} P_{\lambda/\mu}[Y]P_{\mu}[X], \\
Q_{\lambda}(X + Y) &= \sum_{\mu} Q_{\lambda/\mu}[Y]Q_{\mu}[X],
\end{align*}
\[ \sum_{\lambda} P_{\lambda}(X)Q_{\lambda}(Y) = \prod_{i,j=1}^{n} \frac{(txiy_j)_{\infty}}{(x_iy_j)_{\infty}}, \]
\[ Q_{\lambda/\mu}(X) = \sum_{\nu} f_{\mu\nu}^\lambda Q_\nu(X). \]
and
\begin{equation}
P_\mu(X)P_\nu(X) = \sum_\lambda \beta_{\mu\nu}^\lambda P_\lambda(X).
\end{equation}

2.3. Generalised evaluation symmetry. One of the many striking results in Macdonald polynomial theory — first proved in unpublished work by Koornwinder — is the evaluation symmetry
\begin{equation}
P_\lambda(\langle \mu \rangle) = P_\mu(\langle \lambda \rangle).
\end{equation}
where \(\lambda\) and \(\mu\) are partitions of length at most \(n\). As we shall see in Section 2.5, a simple generalisation of this result is the key to proving Theorem 1.2. Before stating this generalisation we put \((2.8)\) in plethystic notation as
\[ P_\lambda \left[ \frac{1-t^n}{1-t} \right] P_\mu(\langle \lambda \rangle) = P_\mu \left[ \frac{1-t^n}{1-t} \right] P_\lambda(\langle \mu \rangle), \]
where
\[ f[\langle \lambda \rangle] = f[q^{\mu_1}t^{n-1} + \ldots + q^{\mu_n}t^0] = f(q^{\lambda_1}t^{n-1}, \ldots, q^{\lambda_n}t^0) = f(\langle \lambda \rangle). \]

**Proposition 2.1** (Generalised evaluation symmetry. I). For \(\lambda\) and \(\mu\) partitions of length at most \(n\),
\begin{equation}
P_\lambda \left[ \frac{1-at^{nm}}{1-t} \right] P_\mu \left[ a(\lambda) + \frac{1-a}{1-t} \right] = P_\mu \left[ \frac{1-at^{nm}}{1-t} \right] P_\lambda \left[ a(\mu) + \frac{1-a}{1-t} \right].
\end{equation}

**Proof.** Both sides are polynomials in \(a\) of degree \(|\lambda|+|\mu|\) with coefficients in \(\mathbb{Q}(q,t)\). It thus suffices to verify \((2.9)\) for \(a = t^p\), where \(p\) ranges over the nonnegative integers. We now write \(\langle \lambda \rangle = \langle \lambda \rangle_n\) and use that
\[ f[a(\lambda)_n + \frac{1-a}{1-t}]_{a=t^p} = f[\langle \lambda \rangle_{n+p}], \]
where, since \(l(\lambda) \leq n\),
\[ f[\langle \lambda \rangle_{n+p}] = f(q^{\lambda_1}t^{p-1} + \ldots + q^{\lambda_n}t^{p-1}, t^0). \]
As a result we obtain
\[ P_\lambda(\langle 0 \rangle_{n+p})P_\mu(\langle \lambda \rangle_{n+p}) = P_\mu(\langle 0 \rangle_{n+p})P_\lambda(\langle \mu \rangle_{n+p}) \]
which follows from ordinary evaluation symmetry for Macdonald polynomials on \((n+p)\)-letter alphabets. \(\square\)

The generalised evaluation symmetry can also be stated without resorting to plethystic notation as a symmetry for skew Macdonald polynomials.

**Proposition 2.2** (Generalised evaluation symmetry. II).
\begin{equation}
(at^n)_\lambda \sum_\nu (a)_\nu Q_{\mu/\nu}(a(\lambda)) = (at^n)_\mu \sum_\nu (a)_\nu Q_{\lambda/\nu}(a(\mu)).
\end{equation}
When \(a = 1\) both sums vanish unless \(\nu = 0\). Thanks to the principal specialisation formula [16] page 337
\begin{equation}
Q_\lambda(\langle 0 \rangle) = (t^n)_\lambda
\end{equation}
the \(a = 1\) case of \((2.10)\) thus corresponds to \((2.8)\) in the equivalent form
\[ \frac{Q_\lambda(\langle \mu \rangle)}{Q_\lambda(\langle 0 \rangle)} = \frac{Q_\mu(\langle \lambda \rangle)}{Q_\mu(\langle 0 \rangle)}. \]
Proof of Proposition 2.2. By changing normalisation we may replace \((P_\lambda, P_\mu)\) in (2.9) by \((Q_\lambda, Q_\mu)\). Using [16, page 338] (2.12) \((a)_\lambda = Q_\lambda \left[ \frac{1-a}{1-t} \right] \) (for \(a = t^n\) this is (2.11)) and (2.4b) this gives rise to
\[
(at^n)_\lambda \sum_\nu Q_{\mu/\nu}[a(\lambda)]Q_\nu \left[ \frac{1-a}{1-t} \right] = (at^n)_\mu \sum_\nu Q_{\lambda/\nu}[a(\mu)]Q_\nu \left[ \frac{1-a}{1-t} \right]
\]
Once again using (2.12) and dispensing with the remaining plethystic brackets yields (2.10). 

2.4. \textit{sl}_n basic hypergeometric series. Before we deal with the most important application of the generalised evaluation symmetry — the proof of Theorem 1.2 — we will show how it implies a multivariable generalisation of Heine’s transformation formula.

Let 
\[ \tau_\lambda = \tau_\lambda(q,t) := (-1)^{|\lambda|} q^{n(\lambda)} t^{-n(\lambda)} \]
and \(X = \{x_1, \ldots, x_n\}\). Then the \(\text{sl}_n\) basic hypergeometric series \(r\Phi_s\) is defined as
\[
\Phi_s \left[ \begin{array}{c} a_1, \ldots, a_r \\ b_1, \ldots, b_s \\ \end{array} \right] = \sum_\lambda \left( \begin{array}{c} a_1, \ldots, a_r \\ b_1, \ldots, b_s \\ \end{array} \right)_\lambda \tau_\lambda^{s-r+1} P_\lambda(X).
\]
For \(n = 1\) this is in accordance with the standard definition of single-variable basic hypergeometric series \(r\phi_s\) as may be found in [15]:
\[
r\Phi_s \left[ \begin{array}{c} a_1, \ldots, a_r \\ b_1, \ldots, b_s \\ \end{array} ; z \right] = \sum_{k=0}^{\infty} \left( \begin{array}{c} a_1, \ldots, a_r \\ b_1, \ldots, b_s \\ \end{array} \right)_k \left( -1 \right)^k q^k \left( \frac{z}{q} \right)^{s-r+1} z^k
\]

where in the second line the \(q\)-dependence of the \(r\phi_s\) series has been suppressed.

Theorem 2.3 (\(\text{sl}_m - \text{sl}_n\) transformation formula). Let \(X = \{x_1, \ldots, x_n\}\) and \(Y = \{y_1, \ldots, y_m\}\). Then
\[
m+1\Phi_m \left[ \begin{array}{c} a, ay_1/t, \ldots, ay_m/t \\ ay_1, \ldots, ay_m \\ \end{array} ; X \right] = \left( \prod_{i=1}^{n} \frac{(ax_i)_\infty}{(x_i)_\infty} \right) \left( \prod_{j=1}^{m} \frac{(y_j)_\infty}{(ay_j)_\infty} \right) n+1\Phi_n \left[ \begin{array}{c} a, ax_1/t, \ldots, ax_n/t \\ ax_1, \ldots, ax_n \\ \end{array} ; Y \right].
\]
For \(m = 0\) this is the \(q\)-binomial theorem for Macdonald polynomials [13] [17]
\[
1\Phi_0 \left[ \begin{array}{c} a \\ \end{array} ; X \right] = \prod_{i=1}^{n} \frac{(ax_i)_\infty}{(x_i)_\infty}
\]
and for \(m = n = 1\) it is Heine’s \(2\phi_1\) transformation formula [5] Equation (III.2)
\[
2\phi_1 \left[ \begin{array}{c} a, ay/t \\ ay \\ \end{array} ; x \right] = \frac{(y, ax)_\infty}{(x, ay)_\infty} 2\phi_1 \left[ \begin{array}{c} a, ax/t \\ ax \\ \end{array} ; y \right].
\]
Proof of Theorem 2.3. First assume that \( m = n \), multiply (2.10) by \( P_\lambda(X)P_\mu(Y) \) and sum over \( \lambda \) and \( \mu \) to get

\[
(2.15) \quad \sum_{\nu,\mu,\lambda} (a)_{\nu}(at^n)_{\lambda}Q_{\mu/\nu}(a(\lambda))P_\lambda(X)P_\mu(Y) = \sum_{\nu,\mu,\lambda} (a)_{\nu}(at^n)_{\mu}Q_{\lambda/\nu}(a(\mu))P_\lambda(X)P_\mu(Y).
\]

If we multiply (2.7) by \( P_\nu(Y) \) and sum over \( \nu \) then (2.5) and (2.6) permit this \( \nu \)-sum to be carried out explicitly on both sides. As a result we obtain the skew Cauchy identity (see also [10, page 352])

\[
(2.16) \quad \sum_{\lambda} P_\lambda(X)Q_{\lambda/\mu}(Y) = P_\mu(X) \prod_{i,j=1}^{n} \frac{(tx_i y_j)_{\infty}}{(x_i y_j)_{\infty}}.
\]

Applying this to (2.15) we can perform the sum over \( \mu \) on the left and the sum over \( \lambda \) on the right, leading to

\[
\sum_{\nu,\lambda} (a)_{\nu}(at^n)_{\lambda}P_\lambda(X)P_\nu(Y) \prod_{i,j=1}^{n} \frac{(aty_i(\lambda)_j)_{\infty}}{(ay_i(\lambda)_j)_{\infty}} = \sum_{\nu,\mu} (a)_{\nu}(at^n)_{\mu}P_\mu(Y)P_\nu(X) \prod_{i,j=1}^{n} \frac{(atx_i(\mu)_j)_{\infty}}{(ax_i(\mu)_j)_{\infty}}.
\]

Using the \( q \)-binomial theorem (2.14) to perform both sums over \( \nu \) gives

\[
\sum_{\lambda} (at^n)_{\lambda}P_\lambda(X) \prod_{i=1}^{n} \frac{(ay_i)_{\infty}}{(y_i)_{\infty}} \prod_{i,j=1}^{n} \frac{(aty_i(\lambda)_j)_{\infty}}{(ay_i(\lambda)_j)_{\infty}} = \sum_{\mu} (at^n)_{\mu}P_\mu(Y) \prod_{i=1}^{n} \frac{(ax_i)_{\infty}}{(x_i)_{\infty}} \prod_{i,j=1}^{n} \frac{(atx_i(\mu)_j)_{\infty}}{(ax_i(\mu)_j)_{\infty}}.
\]

Simplifying the products and replacing \( a \mapsto at^{-n} \) completes the proof of the theorem for \( m = n \).

The general \( m, n \) case trivially follows from \( m = n \); assuming without loss of generality that \( m \leq n \) we set \( y_{m+1}, \ldots, y_n = 0 \) and use that

\[
P_\lambda(y_1, \ldots, y_m, 0, \ldots, 0) = \begin{cases} P_\lambda(y_1, \ldots, y_m) & \text{if } l(\lambda) \leq m, \\ 0 & \text{if } l(\lambda) > m. \end{cases}
\]

2.5. Proof of Theorem 1.2. Using the generalised evaluation symmetry to prove Theorem 1.2 is much more difficult than the proof of Theorem 2.3 and we proceed by first proving an identity for skew Macdonald polynomials.

Theorem 2.4. For \( \lambda \) and \( \mu \) partitions of length at most \( n \),

\[
\sum_{\nu} t^{-|\nu|} \frac{1-a}{1-t} \frac{1-q/ax}{1-t} Q_{\nu/\mu}(a(\lambda))P_{\lambda/\nu}(a(\mu)) = t^{-n|\mu|} \frac{1-at^n}{1-t} \frac{1-(qt^{n-1}/a)}{1-t} \prod_{i,j=1}^{n} \frac{(qt^{i-1}/a)_{\lambda_i-\mu_j}}{(qt^{j-1}/a)_{\lambda_j-\mu_j}}.
\]
Recalling (2.12) and (2.3) it follows that the right-hand side is completely factorised. Moreover, for \( a = 1 \) the summand vanishes unless \( \nu = \mu \) so that we recover the known factorisation of \( Q_{\lambda/\mu}[(1 - q/t)/(1 - t)] \), see [21, Equation (8.20)] or [28, Proposition 3.2]:

\[
Q_{\lambda/\mu} \left[ \frac{1 - q/t}{1 - t} \right] = t^{(1-n)|\mu|}(qt^{n-1})^\lambda P_{\mu}(\langle 0 \rangle) \prod_{i,j=1}^n \frac{(qt^{i-j-1})_{\lambda_i-\mu_j}}{(qt^{j-i-1})_{\lambda_j-\mu_i}}.
\]

**Proof.** In the first few steps we follow the proof of Theorem 2.3 but in an asymmetric manner. That is, we take (2.10), multiply both sides by \( P_\lambda(X) \) and sum over \( \lambda \).

By the Cauchy identity (2.10) followed by the \( q \)-binomial theorem (2.14) we can perform both sums on the right to find

\[
(2.17) \quad \sum_{\lambda,\nu} (at^n)^\lambda (a)_\nu Q_{\mu/\nu}(a(\lambda))P_\lambda(X) = (at^n)_\mu \prod_{i=1}^n (ax_i)_\infty \prod_{i,j=1}^n (atx_i(\mu)_j)_\infty.
\]

On the left we use (2.12) and (2.4b) (twice) to rewrite the sum over \( \nu \) as

\[
\sum_{\nu} (a)_\nu Q_{\mu/\nu}(a(\lambda)) = Q_{\mu} \left[ a(\lambda) + \frac{1-a}{1-t} \right] = \sum_{\nu} Q_{\mu/\nu} \left[ \frac{1-a}{1-t} \right] Q_{\nu}(a(\lambda)).
\]

On the right we use (2.12) to trade \( (at^n)_\mu \) for \( Q_{\mu}[(1 - at^n)/(1 - t)] \). Also renaming the summation index \( \lambda \) as \( \omega \), (2.17) thus takes the form

\[
(2.18) \quad \sum_{\nu,\omega} (at^n)_\omega Q_{\mu/\nu}(a(\omega))P_\omega(X) = Q_{\mu} \left[ \frac{1-at^n}{1-t} \right] \prod_{i=1}^n \langle ax_i \rangle_\infty \prod_{i,j=1}^n \langle atx_i(\mu)_j \rangle_\infty.
\]

By (2.3) it readily follows that we may replace all occurrences of \( Q \) in the above by \( P \). Then specialising \( X = b(\lambda) \) we find

\[
(2.18) \quad \sum_{\nu,\omega} (at^n)_\omega P_{\mu/\nu} \left[ \frac{1-a}{1-t} \right] P_{\nu}(a(\omega))P_\omega(b(\lambda))
\]

\[
= P_{\mu} \left[ \frac{1-at^n}{1-t} \right] \prod_{i=1}^n \langle ab(\lambda)_i \rangle_\infty \prod_{i,j=1}^n \langle abt(\lambda)_i(\mu)_j \rangle_\infty.
\]

The next few steps focus on the left-hand side of this identity. First, by homogeneity followed by an application of the evaluation symmetry (2.8),

\[
\text{LHS} (2.18) = \sum_{\nu,\omega} a^{(\nu)}b^{(\omega)}(at^n)_\omega P_{\mu/\nu} \left[ \frac{1-a}{1-t} \right] P_{\omega}(\langle 0 \rangle) P_\lambda(\langle 0 \rangle) P_{\lambda}(\langle 0 \rangle) P_{\lambda}(\langle 0 \rangle) P_{\nu}(\langle 0 \rangle).
\]

Using (2.7) this can be further rewritten as

\[
\text{LHS} (2.18) = \sum_{\eta,\nu,\omega} a^{(\nu)}b^{(\omega)}(at^n)_\omega f_{\lambda,\nu}^\eta P_{\mu/\nu} \left[ \frac{1-a}{1-t} \right] P_{\omega}(\langle 0 \rangle) P_\lambda(\langle 0 \rangle) P_{\lambda}(\langle 0 \rangle) P_{\nu}(\langle 0 \rangle).
\]

By another appeal to evaluation symmetry this yields

\[
\text{LHS} (2.18) = \sum_{\eta,\nu,\omega} a^{(\nu)}b^{(\omega)}(at^n)_\omega f_{\lambda,\nu}^\eta P_{\mu/\nu} \left[ \frac{1-a}{1-t} \right] P_{\nu}(\langle 0 \rangle) P_\lambda(\langle 0 \rangle) P_{\lambda}(\langle 0 \rangle) P_{\lambda}(\langle 0 \rangle) P_{\omega}(\langle 0 \rangle).
\]
The sum over $\omega$ can now be performed by (2.14) so that
\[
\text{LHS}(2.18) = \sum_{\eta,\nu} a^{[\nu]} f^\eta_{\lambda,\mu/\nu} \left[ \frac{1-a}{1-t} \right] P_\eta(\langle 0 \rangle) \prod_{i=1}^n \left( \frac{ab^{n-i+j+1} \lambda_i + \mu_j}{ab^{n-i+j+2} \lambda_i + \mu_j} \right).
\]
Equating this with the right-hand side of (2.18), manipulating the (infinite) $q$-Lemma 2.5. line the proof given below we first prepare an easy lemma.

By (2.6) and (2.12)
\[
\left|\eta,\nu\right|\text{as well as the fact that the summand vanishes unless }\left|\nu\right| = \left|\lambda\right|, \text{we end up with}
\sum_{\eta,\nu} t^{-[\nu]} (q/\nu) f^\eta_{\lambda,\mu/\nu} \left[ \frac{1-a}{1-t} \right] = t^{-n[\nu]} (qt^{n-1}/a) \lambda \prod_{i<j} \left( \frac{qt^{j-i+1}/a}{qt^{j-i+2}/a} \right) \lambda_i - \mu_j.
\]
By (2.6) and (2.12)
(2.19) \[
\sum_{\nu} (b)_{\nu} f^\lambda_{\mu/\nu} = \sum_{\nu} f^\lambda_{\mu/\nu} Q_{\nu} = Q_{\lambda/\mu} \left[ \frac{1-b}{1-t} \right],
\]
so that the sum over $\eta$ can be performed. By a final appeal to (2.12) the proof is done.

Equipped with Theorem 2.4 it is not difficult to prove Theorem 1.2. To streamline the proof given below we first prepare an easy lemma.

**Lemma 2.5.** For $X = \{x_1, \ldots, x_n\}$ and $\mu$ a partition of length at most $n$,
\[
\sum_{\lambda} Q_{\lambda/\mu} \left[ \frac{a-b}{1-t} \right] P_\lambda(X) = P_\mu(X) \prod_{i=1}^n \frac{(bx_i)_{\infty}}{(ax_i)_{\infty}}.
\]
and

\[ \sum_{\lambda} P_{\lambda/\mu} \left[ \frac{a - b}{1 - t} \right] Q_{\lambda}(X) = Q_{\mu}(X) \prod_{i=1}^{n} \frac{(bx_{i})_{\infty}}{(ax_{i})_{\infty}}. \]

For \( \mu = 0 \) this is just the \( q \)-binomial theorem (2.14) for Macdonald polynomials.

**Proof.** By (2.3) the two identities are in fact one and the same result and we only need to prove the first claim. To achieve this we multiply (2.19) by \( P_{\lambda}(aX) \) and sum over \( \lambda \). By (2.7) and homogeneity this yields

\[ P_{\mu}(X) \sum_{\nu} (b)_{\nu} P_{\nu}(aX) = \sum_{\lambda} Q_{\lambda/\mu} \left[ \frac{a - ab}{1 - t} \right] P_{\lambda}(X). \]

On the left we can sum over \( \nu \) using the \( q \)-binomial theorem (2.14) leading to the desired result (with \( b \mapsto ab \)). \( \square \)

**Proof of Theorem 1.3** Elementary manipulations show that the theorem is invariant under the simultaneous changes \( n \leftrightarrow m, tX \leftrightarrow Y \) and \( a \leftrightarrow qt/a \). Without loss of generality we may thus assume that \( m \leq n \). But

\[ (at^{n-1})_{\lambda} \prod_{i,j=1}^{n} \frac{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}}{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}} \bigg|_{\mu_{m+1} = \cdots = \mu_{n} = 0} = (at^{m-1})_{\lambda} \prod_{i=1}^{m} \prod_{j=1}^{m} \frac{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}}{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}} \]

so that the case \( m < n \) follows from the case \( m = n \) by setting \( y_{m+1} = \cdots = y_{n} = 0 \).

In the remainder we assume that \( m = n \), in which case the theorem simplifies to

\[ (2.20) \quad \sum_{\lambda,\mu} t^{[\lambda - n]_{\mu}} P_{\lambda}(X) P_{\mu}(Y) \frac{(at^{n-1})_{\lambda}(qt^{n}/a)_{\mu}}{(at^{n-1})_{\lambda}^{(n)}_{\mu}} \prod_{i,j=1}^{n} \frac{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}}{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}} = \prod_{i=1}^{n} \frac{(ax_{i})_{\infty}}{(tx_{i})_{\infty}} \prod_{j=1}^{n} \frac{(qy_{j}/a)_{\infty}}{(y_{j})_{\infty}} \prod_{i,j=1}^{n} \frac{(tx_{i}y_{j})_{\infty}}{(x_{i}y_{j})_{\infty}}. \]

To prove this we take Theorem 2.4 replace \( a \mapsto q/a \), multiply both sides by

\[ t^{[\lambda]} P_{\lambda}(X) Q_{\mu}(Y) \]

and sum over \( \lambda \) and \( \mu \). Hence

\[ \sum_{\lambda,\mu,\nu} P_{\lambda}(X) Q_{\mu}(Y) P_{\mu/\nu} \left[ \frac{1 - q/a}{1 - t} \right] Q_{\lambda/\nu} \left[ \frac{t - a}{1 - t} \right] = \sum_{\lambda,\mu} t^{[\lambda - n]_{\mu}} P_{\lambda}(X) Q_{\mu}(Y) (at^{n-1})_{\lambda} P_{\mu} \left[ \frac{1 - qt^{n}/a}{1 - t} \right] \prod_{i,j=1}^{n} \frac{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}}{(at^{j-i-1})_{\lambda_{i} - \mu_{j}}}. \]

On the right we apply (2.3) and (2.12) to rewrite

\[ Q_{\mu}(Y) P_{\mu} \left[ \frac{1 - qt^{n}/a}{1 - t} \right] = (qt^{n}/a)_{\mu} P_{\mu}(Y), \]
and on the left we employ Lemma 2.5 to carry out the sums over \( \lambda \) and \( \mu \). Hence

\[
\sum_{\nu} P_{\nu}(X)Q_{\nu}(Y) \prod_{i=1}^{n} \frac{(ax_i)^{\infty}}{(tx_i)^{\infty}} \prod_{j=1}^{n} \frac{(qy_j/a)^{\infty}}{(y_j)^{\infty}} = \sum_{\lambda,\mu} \lambda^{|\mu|} \nu_{\lambda}(X) P_{\mu}(Y) (a t^{n-1})^{\mu} (qt^{n-1})^{\lambda} \prod_{i,j=1}^{n} \frac{(at^{j-i-1})_{\lambda_i - \mu_j}}{(at^{j-i-1})_{\lambda_i - \mu_j}}.
\]

Performing the remaining sum on the left by (2.5) results in (2.20). \( \square \)

We conclude this section with a remark about a generalisation of Theorem 1.2. Let \( X = \{x_1, \ldots, x_n\} \) and let \( \lambda \) be a partition of length \( n \). Then

\[
P_{\lambda}(X) = x_1 \cdots x_n P_{\mu}(X),
\]

where \( \mu = (\lambda_1 - 1, \ldots, \lambda_n - 1) \). Now let \( P \) denote the set of weakly decreasing integer sequences of finite length. Then we may turn things around and use the above recursion to extend \( P_{\lambda} \) to all \( \lambda \in P \). It is then readily verified that

\[
(qt^{n-1})_{\lambda} P_{\lambda}(X) = t^{n(\lambda)} \frac{(q^{m-1})_{\lambda}}{c_\lambda} P_{\lambda}(X)
\]

is well-defined for \( \lambda \in P \) (unlike \( P_{\lambda}(X) \)).

We now state without proof the following generalisation of Theorem 1.2.

**Theorem 2.6.** Let \( X = \{x_1, \ldots, x_n\} \) and \( Y = \{y_1, \ldots, y_m\} \). Then

\[
\sum_{\lambda \in P} \mu \sum_{\mu} \lambda^{|\mu|} \nu_{\lambda}(X) P_{\mu}(Y) \frac{(at^{m-1})_{\lambda} (bt^{n-1})_{\mu}}{(ab t^{m-1})_{\lambda} (ab t^{n-1})_{\mu}} \prod_{i=1}^{n} \prod_{j=1}^{m} \frac{(at^{j-i-1})_{\lambda_i - \mu_j}}{(at^{j-i-1})_{\lambda_i - \mu_j}}
\]

For \( m = 0 \) this reduces to Kaneko’s \( \Psi_1 \) sum for Macdonald polynomials \( \Psi_1 \) and for \( n = 0 \) to the \( \Psi_0 \) sum (2.14). When \( ab = q \) the summand on the left vanishes unless \( \lambda \) is an actual partition and we recover Theorem 1.2.

### 3. The \( s_3 \) Selberg integral

#### 3.1. The integration chains \( C_{\beta_1,\gamma_1}^{k_1,k_2}[0,1] \) and \( C_{\gamma_1}^{k_1,k_2}[0,1] \)

Before proving Theorem 1.3 we give two descriptions of the chain \( C_{\beta_1,\gamma_1}^{k_1,k_2}[0,1] \). We also identify the special case \( \beta = 1 \) with the chain \( C_{\gamma_1}^{k_1,k_2}[0,1] \) defined by Tarasov and Varchenko in [25].

Let

\[
I^{k_1,k_2}[0,1] = \{ (x_1, \ldots, x_{k_1}, y_1, \ldots, y_{k_2}) \in \mathbb{R}^{k_1+k_2} : 0 < x_1 < \cdots < x_{k_1} < 1 \quad \text{and} \quad 0 < y_1 < \cdots < y_{k_2} < 1 \},
\]

and fix a total ordering among the \( x_i \) and \( y_j \) as follows. Let \( a = (a_1, \ldots, a_{k_1}) \) be a weakly increasing sequence of nonnegative integers not exceeding \( k_2 \): \( a = (a_1, \ldots, a_{k_1}) \) be a

\[
0 \leq a_1 \leq \cdots \leq a_{k_1} \leq k_2.
\]

Then the domain \( I_{a}^{k_{1}, k_{2}}[0, 1] \subseteq I_{k_{1}, k_{2}}[0, 1] \) is formed by imposing the additional inequalities

\[
x_i < y_{a_i+1} < y_{a_i+2} < \cdots < y_{a_i+1} < x_{i+1} \quad \text{for} \ 0 \leq i \leq k_1,
\]

where \( x_0 := 0, x_{k_{1}+1} := 1, a_{0} := 0 \) and \( a_{k_{1}+1} := k_{2} \). Equivalently,

\[
\begin{cases} 
0 < y_1 < y_2 < \cdots < y_n < x_i \\
x_i < y_{a_i+1} < \cdots < y_{k_{2}-1} < y_{k_{2}} < 1
\end{cases}
\quad \text{for} \ 1 \leq i \leq k_1.
\]

Clearly, as a chain,

\[
I_{k_{1}, k_{2}}[0, 1] = \sum_{a} I_{a}^{k_{1}, k_{2}}[0, 1],
\]

where the sum is over all sequences \( a = (a_1, \ldots, a_{k_{2}}) \) satisfying (3.2). To lift \( I_{k_{1}, k_{2}}[0, 1] \) to \( C^{k_{1}, k_{2}}_{\beta, \gamma}[0, 1] \) we replace the right-hand side of (3.4) by a weighted sum:

\[
C^{k_{1}, k_{2}}_{\beta, \gamma}[0, 1] = \sum_{a} \left( \prod_{i=1}^{k_{2}} \frac{\sin \pi (\beta - (i - a_i - k_1 + k_2)\gamma)}{\sin \pi (\beta - (i - k_1 + k_2)\gamma)} \right) I_{a}^{k_{1}, k_{2}}[0, 1],
\]

where it is assumed that \( \beta, \gamma \in \mathbb{C} \) such that

\( \beta + (i - k_{2} - 1)\gamma \notin \mathbb{Z} \) \quad \text{for} \ 1 \leq i \leq \min\{k_1, k_2\}.

This is a necessary and sufficient condition for

\[
\prod_{i=1}^{k_{2}} \frac{\sin \pi (\beta - (i - a_i - k_1 + k_2)\gamma)}{\sin \pi (\beta - (i - k_1 + k_2)\gamma)}
\]

to be free of poles for all admissible sequences \( a \).

By viewing \((a_{k_{1}}, \ldots, a_{2}, a_{1})\) as a partition with largest part not exceeding \( k_2 \) and length not exceeding \( k_1 \), the operations of conjugation and/or complementation yield several alternative descriptions of the chain (3.5). Below we give one such description, reflecting the \( \mathbb{Z}_2 \) symmetry of Theorem 1.3 with respect to the interchange of the labels 1 and 2 in \( k_1, a_i \) and \( \beta_i \).

Assume (3.1) and fix a total ordering among the \( x_i \) and \( y_i \) as follows. Let \( b = (b_1, \ldots, b_{k_2}) \) be a weakly increasing sequence of nonnegative integers not exceeding \( k_1 \):

\[
0 \leq b_1 \leq \cdots \leq b_{k_2} \leq k_1.
\]

Then the domain \( \tilde{I}_{b}^{k_{1}, k_{2}}[0, 1] \subseteq I_{k_{1}, k_{2}}[0, 1] \) is formed by assuming the further inequalities

\[
y_i < x_{b_{i+1}} < x_{b_{i}+2} < \cdots < x_{b_{i}+1} < y_{i+1} \quad \text{for} \ 0 \leq i \leq k_2,
\]

where \( y_0 := 0, y_{k_{2}+1} := 1, b_{0} := 0 \) and \( b_{k_{2}+1} := k_{1} \). It is easily seen that if \( \mu = (b_{k_{2}}, \ldots, b_{1}) \) and \( \lambda = (a_{k_{2}}, \ldots, a_{1}) \), then \( \mu' \) is the conjugate of \( \lambda \) with respect to \( (k_2^2) \), i.e., \( \mu_i' = k_2 - k_{i+1} = k_2 - a_i \) for \( 1 \leq i \leq k_1 \). Hence, for a pair of admissible sequences \((a, b)\) related by “conjugation–complementation”,

\[
\tilde{I}_{b}^{k_{1}, k_{2}}[0, 1] = I_{a}^{k_{1}, k_{2}}[0, 1]
\]

and

\[
\prod_{i=1}^{k_{2}} \frac{\sin \pi (\beta + (i - b_i + k_{1} - k_2 - 1)\gamma)}{\sin \pi (\beta + (i - k_2 - 1)\gamma)} = \prod_{i=1}^{k_1} \frac{\sin \pi (\beta - (i - a_i - k_1 + k_2)\gamma)}{\sin \pi (\beta - (i - k_1 + k_2)\gamma)}.
\]
In other words,

\begin{equation}
C^{k_1,k_2}_{\beta,\gamma}[0,1] = \sum_b \left( \prod_{i=1}^{k_2} \frac{\sin \pi \left( \frac{\beta + (i - b_i + k_1 - k_2 - 1)\gamma}{\beta + (i - k_2 - 1)\gamma} \right)}{\sin \pi \left( \frac{\beta + (i - k_2 - 1)\gamma}{\beta + (i - k_2 - 1)\gamma} \right)} \right) I_b^{k_1,k_2}[0,1]
\end{equation}

summed over all sequences $b = (b_1, \ldots, b_{k_2})$ subject to (3.6). Comparing (3.5) and (3.7), and using that for $\beta_1 + \beta_2 = \gamma + 1$,

\begin{equation}
\prod_{i=1}^{k_1} \frac{\sin \pi (\beta_1 - (i - k_1 + k_2)\gamma)}{\sin \pi (\beta_2 + (i - k_1 - 1)\gamma)} = \prod_{i=0}^{k_1-1} \frac{\Gamma(\beta_1 + i\gamma)}{\Gamma(\beta_1 + (i + 1)\gamma)} \prod_{i=0}^{k_2-1} \frac{\Gamma(\beta_2 + (i - k_1)\gamma)}{\Gamma(\beta_2 + i\gamma)}
\end{equation}

it readily follows that the symmetry relation (1.5) holds.

To conclude this section we consider (3.5) for $\beta = 1$:

\begin{equation}
C^{k_1,k_2}_{1,\gamma}[0,1] = \sum_a \left( \prod_{i=1}^{k_1} \frac{\sin \pi ((i - a_i - k_1 + k_2)\gamma)}{\sin \pi ((i - k_1 + k_2)\gamma)} \right) I_a^{k_1,k_2}[0,1].
\end{equation}

The summand vanishes if $a_i = i - k_1 + k_2$ for some $1 \leq i \leq k_1$ so that we may add the additional restrictions

\[ a_i \neq i - k_1 + k_2 \quad \text{for } 1 \leq i \leq k_1 \]

to the sum over $a$. Recalling (3.2) this in fact implies that the much stronger

\[ a_i < i - k_1 + k_2 \quad \text{for } 1 \leq i \leq k_1. \]

Therefore,

\begin{equation}
C^{k_1,k_2}_{1,\gamma}[0,1] = \sum_{a_i < i-k_1+k_2} \left( \prod_{i=1}^{k_1} \frac{\sin \pi ((i - a_i - k_1 + k_2)\gamma)}{\sin \pi ((i - k_1 + k_2)\gamma)} \right) I_a^{k_1,k_2}[0,1].
\end{equation}

Defining $M(i) = a_i + 1$, so that

\[ 1 \leq M(1) \leq M(2) \leq \cdots \leq M(k_1) \leq k_2 \]

and

\[ M(i) \leq i - k_1 + k_2 \quad \text{for } 1 \leq i \leq k_1, \]

and writing $M = (M(1), \ldots, M(k_1))$, we finally obtain

\begin{equation}
C^{k_1,k_2}_{1,\gamma}[0,1] = \sum_M \left( \prod_{i=1}^{k_1} \frac{\sin \pi ((i - M(i) - k_1 + k_2 + 1)\gamma)}{\sin \pi ((i - k_1 + k_2)\gamma)} \right) I_M^{k_1,k_2}[0,1] =: C^{k_1,k_2}_{1,\gamma}[0,1].
\end{equation}

In the above, by abuse of notation, $I_M^{k_1,k_2}[0,1] = I_a^{k_1,k_2}[0,1]$ if $M = (a_1 + 1, \ldots, a_{k_1} + 1)$. The chain $C^{k_1,k_2}_{1,\gamma}[0,1]$ is precisely that of Tarasov and Varchenko (up to an interchange of $k_1$ and $k_2$), see [25, page 177].
3.2. Proof of Theorem 1.3. We are now prepared to prove Theorem 1.3. In fact, we will prove a more general integral, generalising Kadell’s extension of the Selberg integral [10] to \( sl_3 \). To shorten some of the subsequent equations we introduce another normalised Macdonald polynomial, and for \( X = \{ x_1, \ldots, x_n \} \)

\[
\tilde{P}_\lambda(X) = \frac{P_\lambda(X)}{P_\lambda(\{0\})} = \frac{P_\lambda(X)}{P_\lambda(\{0\})}.
\]

Similarly we define a (normalised) Jack polynomial as

\[
\tilde{P}_\lambda^{(\alpha)}(X) = \lim_{q \to 1} \tilde{P}_\lambda(X; q^\alpha, q).
\]

Hence

\[
\tilde{P}_\lambda^{(\alpha)}(X) = \frac{P^{(\alpha)}_\lambda(X)}{P^{(\alpha)}_\lambda(1^n)}
\]

where \( P^{(\alpha)}_\lambda(X) \) is the Jack polynomial [16, 24].

**Theorem 3.1.** Set \( X = \{ x_1, \ldots, x_k \} \), \( Y = \{ y_1, \ldots, y_{k_2} \} \),

\[
dX = dx_1 \cdots dx_k, \quad \text{and} \quad dY = dy_1 \cdots dy_{k_2}.
\]

For \( \alpha_1, \alpha_2, \beta_1, \beta_2, \gamma \in \mathbb{C} \) such that \( |\gamma| \) is sufficiently small,

\[
\min\{ \Re(\alpha_1) + \lambda_{k_1}, \Re(\alpha_2) + \mu_{k_2}, \Re(\beta_1), \Re(\beta_2) \} > 0,
\]

and

\[
\beta_1 + (i - k_2 - 1)\gamma \notin \mathbb{Z} \quad \text{for} \quad 1 \leq i \leq \min\{k_1, k_2\}
\]

there holds

\[
\int_{C_{\beta_1, \gamma} \{0,1\} [0,1]} \tilde{P}^{(1/\gamma)}_\lambda(X) \tilde{P}^{(1/\gamma)}_\mu(Y) \prod_{i=1}^{k_1} x_i^{\alpha_1-1}(1-x_i)^{\beta_1-1} \prod_{i=1}^{k_2} y_i^{\alpha_2-1}(1-y_i)^{\beta_2-1}
\]

\[
\times \prod_{1 \leq i < j \leq k_1} |x_i - x_j|^{2\gamma} \prod_{1 \leq i < j \leq k_2} |y_i - y_j|^{2\gamma} \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} |x_i - y_j|^{-\gamma} \ dX \ dY
\]

\[
= \prod_{i=1}^{k_1} \frac{\Gamma(\alpha_1 + (k_1 - i)\gamma + \lambda_i) \Gamma(\beta_1 + (i - k_2 - 1)\gamma + \lambda_i) \Gamma(i\gamma)}{\Gamma(\alpha_1 + \beta_1 + (2k_1 - k_2 - i - 1)\gamma + \lambda_i) \Gamma(\gamma)}
\]

\[
\times \prod_{i=1}^{k_2} \frac{\Gamma(\alpha_2 + (k_2 - i)\gamma + \mu_i) \Gamma(\beta_2 + (i - 1)\gamma + \mu_i) \Gamma(i\gamma)}{\Gamma(\alpha_2 + \beta_2 + (2k_2 - k_1 - i - 1)\gamma + \mu_i) \Gamma(\gamma)}
\]

\[
\times \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} \frac{\Gamma(\alpha_1 + \alpha_2 + (k_1 + k_2 - i - j - 1)\gamma + \lambda_i + \mu_j)}{\Gamma(\alpha_1 + \alpha_2 + (k_1 + k_2 - i - j - 1)\gamma + \lambda_i + \mu_j)}.
\]

Theorem 1.3 corresponds to the case special case \( \lambda = \mu = 0 \), and Kadell’s integral arises by taking \( k_1 = 0 \) or \( k_2 = 0 \).
Proof: Throughout the proof $0 < q < 1$.
We take Theorem 1.2 with $(\lambda, \mu)$ replaced by $(\eta, \nu)$ and $(n, m)$ replaced by $(k_1, k_2)$. If we then specialise $X = z(\lambda)_{k_1}$ and $Y = w(\mu)_{k_2}$ and use the evaluation symmetry (2.8) on both Macdonald polynomials in the summand, we obtain

$$
\sum_{\eta, \nu} l^{\eta - k_1, \nu} \hat{P}_\lambda(\langle \eta \rangle_{k_1}) \hat{P}_\mu(\langle \nu \rangle_{k_2}) P_\eta(z(0)_{k_1}) P_\nu(w(0)_{k_2}) \\
\times (at^{k_2-1})^\lambda(q t^{k_1}/a)^\nu \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} (at^{j-1})^{\eta_i - \nu_j} \\
= \prod_{i=1}^{k_1} (az q^{\lambda_i} t^{k_1-i})^{\infty} \prod_{j=1}^{k_2} (w q^{\nu_j} t^{k_2-j}/a)^\infty \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} (w q^{\lambda_i + \mu_j} t^{k_1-i-j})^\infty.
$$

Next we set

$$(z, w, a, t) = (q^{a_1-\gamma}, q^{a_2}, q^{b_1+(k_1-k_2)\gamma}, q^\gamma)$$

and introduce the auxiliary variable $\beta_2$ by $\beta_1 + \beta_2 = \gamma + 1$. Equations (2.1), (2.3) and (2.12) imply the principal specialisation formula

$$
P_\lambda(0) = \frac{t^{2n(\lambda)}}{(q^{n-1})^\lambda} \prod_{1 \leq i < j \leq n} \frac{1 - q^{\lambda_i - \lambda_j} t^{-i}}{1 - t^{-i}} \frac{(t^{j-i})^{\lambda_i - \lambda_j}}{(qt^{j-i})^{\lambda_i - \lambda_j}}.
$$

Using this as well as the definition of the $q$-Gamma function

$$
\Gamma_q(x) = \frac{(q x - 1)}{(1 - q)^{x-1}}, \quad x \in \mathbb{C},
$$

we can rewrite the above identity as

$$(1 - q)^{k_1+k_2} \sum_{\eta, \nu} \hat{P}_\lambda(x_1 q^{(k_1-1)\gamma}, x_2 q^{(k_2-2)\gamma}, \ldots, x_{k_1}) \\
\times \hat{P}_\mu(y_1 q^{(k_2-1)\gamma}, y_2 q^{(k_2-2)\gamma}, \ldots, y_{k_2}) \\
\times \prod_{i=1}^{k_1} x_i^{a_1} (q^{1+(k_1-i)\gamma} x_i)_{\beta_1-i} \prod_{1 \leq j \leq k_1} x_j^{2\gamma} (1 - q^{(j-i)\gamma} x_i/x_j) (q^{1+(j-i-1)\gamma} x_i/x_j)^{2\gamma-1} \\
\times \prod_{i=1}^{k_2} y_i^{a_2} (q^{1+(k_2-i)\gamma} y_i)_{\beta_2-i} \prod_{1 \leq j \leq k_2} y_j^{2\gamma} (1 - q^{(j-i)\gamma} y_i/y_j) (q^{1+(j-i-1)\gamma} y_i/y_j)^{2\gamma-1} \\
\times \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} y_j^{-\gamma} (q^{\beta_1+(k_1-k_2-j)\gamma} x_i/y_j)^{-\gamma}$$

$$
= \prod_{i=1}^{k_1} \frac{\Gamma_q(\alpha_1 + (k_1-i)\gamma + \lambda_i) \Gamma_q(\beta_1 + (i-k_2-1)\gamma)}{\Gamma_q(\alpha_1 + \beta_1 + (2k_1-k_2-i-1)\gamma + \lambda_i) \Gamma_q(\gamma)} \\
\times \prod_{i=1}^{k_2} \frac{\Gamma_q(\alpha_2 + (k_2-i)\gamma + \mu_i) \Gamma_q(\beta_2 + (i-1)\gamma)}{\Gamma_q(\alpha_2 + \beta_2 + (2k_2-k_1-i-1)\gamma + \mu_i) \Gamma_q(\gamma)} \\
\times \prod_{i=1}^{k_1} \prod_{j=1}^{k_2} \frac{\Gamma_q(\alpha_1 + \alpha_2 + (k_1+k_2-i-j-1)\gamma + \lambda_i + \mu_j)}{\Gamma_q(\alpha_1 + \alpha_2 + (k_1+k_2-i-j)\gamma + \lambda_i + \mu_j)}
$$
Here \( x_i := q^{a_i} \) and \( y_i := q^{b_i} \), so that

\[(3.9) \quad 0 < x_1 < \cdots < x_{k_1} \leq 1 \quad \text{and} \quad 0 < y_1 < \cdots < y_{k_2} \leq 1.\]

The above is essentially a \((k_1 + k_2)\)-dimensional \(q\)-integral (more on this in the next section) and all that remains is to let \( q \) tend to 1 from below. The resulting integrand, however, depends sensitively on the relative ordering between the \( x_i \) and \( y_j \). Indeed

\[
\lim_{q \to 1^{-}} y_j^{-\gamma} (q^{\beta_1 + (k_1 - k_2 + j - i)\gamma} x_i / y_j)^{-\gamma} = |x_i - y_j|^{-\gamma} \times \begin{cases} 1 & \text{if } x_i < y_j \\ 1 - j - k_1 + k_2 + 1) \gamma & \sin \pi (\beta_1 - (i - j - k_1 + k_2 + 1) \gamma) \\ \sin \pi (\beta_1 - (i - j - k_1 + k_2) \gamma) \\ \sin \pi (\beta_1 - (i - j - k_1 + k_2 + 1) \gamma) & \text{if } x_i > y_j. \end{cases}
\]

Consequently, before we can take the required limit we must fix a complete ordering among the integration variables (compatible with (3.9)) and sum over all admissible orderings. This is exactly what is done at the beginning of this section and in the remainder we assume that

\[(x_1, \ldots, x_{k_1}, y_1, \ldots, y_{k_2}) \in I^{k_1, k_2}_{a_1, \ldots, a_{k_1}} [0, 1].\]

To find how to weigh this domain we recall that according to (3.3) \( y_{a_i+1} > x_i > y_{a_i} > \cdots > y_1 \). The correct weight is thus

\[
\prod_{i=1}^{k_1} \prod_{j=1}^{a_i} \frac{\sin \pi (\beta_1 - (i - j - k_1 + k_2) \gamma)}{\sin \pi (\beta_1 - (i - j - k_1 + k_2 + 1) \gamma)} = \prod_{i=1}^{k_1} \frac{\sin \pi (\beta_1 - (i - a_i - k_1 + k_2) \gamma)}{\sin \pi (\beta_1 - (i - k_1 + k_2) \gamma)},
\]

in accordance with \( C_{\beta_1, \gamma}^{k_1, k_2} [0, 1] \), see (3.5). \( \square \)

### 4. The Askey–Habsieger–Kadell integral

For \( 0 < q < 1 \) the \( q \)-integral on \([0, 1]\) is defined as

\[(4.1) \quad \int_0^1 f(x) q_x = (1 - q) \sum_{k=0}^{\infty} f(q^k) q^k,
\]

where it is assumed the series on the right converges. When \( q \to 1^- \) the \( q \)-integral reduces, at least formally, to the Riemann integral of \( f \) on the unit interval. An obvious \( n \)-dimensional analogue of (4.1) is

\[
\int_{[0,1]^n} f(X) q_X = (1 - q)^n \sum_{k_1, \ldots, k_n = 0}^{\infty} f(q^{k_1}, \ldots, q^{k_n}) q^{k_1 + \cdots + k_n},
\]

where the multiple sum on the right is assumed to be absolutely convergent and where \( f(X) = f(x_1, \ldots, x_n) \) and \( q_X = q_{x_1} \cdots q_{x_n} \).
In 1980 Askey [2] conjectured a q-analogue of the Selberg integral when the parameter \( \gamma \) is a nonnegative integer, say \( k \):

\[
\int_{[0,1]^n} \prod_{i=1}^{n} x_i^{\alpha_{i-1}}(x_i q)_{\beta_{i-1}} \prod_{1 \leq i < j \leq n} x_i^{2k}(q^{1-k} x_j/x_i)_{2k} \, dq \, X
\]

\[
= q^{\alpha_k(\gamma)+2k^2(\gamma)} \prod_{i=1}^{n} \frac{\Gamma_q(\alpha+ik)\Gamma_q(\beta+ik)\Gamma_q(1+(i+1)k)}{\Gamma_q(\alpha+\beta+(n+i-1)k)\Gamma_q(1+k)},
\]

for \( \text{Re}(\alpha) > 0 \) and \( \beta \neq 0, -1, -2, \ldots \). Askey’s conjecture was proved independently by Habsieger [6] and Kadell [9].

Just as the ordinary Selberg integral, the Askey–Habsieger–Kadell integral can be generalised by the inclusion of symmetric functions in the integrand. Specifically, Kaneko [11] and Macdonald [16] proved that

\[
\frac{\beta(\lambda)}{\Gamma_q(\beta+1)} = \frac{\beta(\lambda-k)}{\Gamma_q(\beta-k+1)}
\]

(4.2) \( \int_{[0,1]^n} \tilde{P}_\lambda(X; q, q^k) \prod_{i=1}^{n} x_i^{\alpha_{i-1}}(x_i q)_{\beta_{i-1}} \prod_{1 \leq i < j \leq n} x_i^{2k}(q^{1-k} x_j/x_i)_{2k} \, dq \, X
\]

\[
= q^{\alpha_k(\gamma)+2k^2(\gamma)} \prod_{i=1}^{n} \frac{\Gamma_q(\alpha+(n-i)k+\lambda_i)\Gamma_q(\beta+(i-1)k)\Gamma_q(1+ik)\Gamma_q(1+k)}{\Gamma_q(\alpha+\beta+(2n-i-1)k+\lambda_i)\Gamma_q(k+1)},
\]

for \( \text{Re}(\alpha) > -\lambda_n \) and \( \beta \neq 0, -1, -2, \ldots \).

The \( \mathfrak{sl}_n - \mathfrak{sl}_m \) transformation formula of Theorem 2.3 allows the for the Askey–Habsieger–Kadell integral as well as its generalisation (4.2) to be extended to a transformation between integrals of different dimensions. For \( \lambda = (\lambda_1, \ldots, \lambda_n) \) and \( \mu = (\mu_1, \ldots, \mu_m) \) define

\[
S_{\lambda \mu}^{(n,m)}(\alpha_1, \alpha_2, \beta; k) = \int_{[0,1]^n} \tilde{P}_\lambda(X; q, q^k) \prod_{i=1}^{n} x_i^{\alpha_{i-1}}(x_i q)_{\beta_{i-1}} \prod_{1 \leq i < j \leq n} x_i^{2k}(q^{1-k} x_j/x_i)_{2k} \, dq \, X
\]

Theorem 4.1. Let \( \lambda = (\lambda_1, \ldots, \lambda_n) \), \( \mu = (\mu_1, \ldots, \mu_m) \) be partitions, \( k \) a nonnegative integer and \( \alpha_1, \alpha_2, \beta \in \mathbb{C} \). Then

\[
S_{\lambda \mu}^{(n,m)}(\alpha_1, \alpha_2, \beta; k) = q^{\alpha_k(\gamma)+2k^2(\gamma)} \prod_{i=1}^{n} \frac{\Gamma_q(\beta+(i-1)k)\Gamma_q(\alpha_1+\lambda_1+(n-i)k)\Gamma_q(1+ik)}{\Gamma_q(\alpha_1+\beta+\lambda_i+(n-m-i)k)\Gamma_q(1+k)},
\]

\[
\times \prod_{i=1}^{n} \prod_{j=1}^{m} \frac{(x_i q)_{\alpha_2+\beta+\mu_i+(m-n-j)k-1} \times \prod_{i=1}^{n} \prod_{j=1}^{m} (x_i q)_{\alpha_2+\beta+\mu_i+(m-n-j)k-1} \times \prod_{i=1}^{n} \prod_{j=1}^{m} \frac{\Gamma_q(\beta+(i-1)k)\Gamma_q(\alpha_2+\lambda_i+(m-n-i)k)\Gamma_q(1+ik)}{\Gamma_q(\alpha_2+\beta+\mu_i+(m-n-i)k)\Gamma_q(1+k)},
\]

for \( \text{Re}(\alpha_1) > -\lambda_n \), \( \text{Re}(\alpha_2) > -\mu_m \), and generic \( \beta \).

By “generic \( \beta \)” it is meant that \( \beta \) should avoid a countable set of isolated singularities. More precisely, \( \beta \) should be such that none of \( \beta-(n-1)k \), \( \beta-(m-1)k \), \( \alpha_1+\beta+\lambda_j+(n-m-j)k \) and \( \alpha_2+\beta+\mu_j+(m-n-j)k \) take nonpositive integer values. Since \( S_{\lambda \mu}^{(0,n)}(\alpha_2, \alpha_1, \beta; k) = 1 \) the \( m = 0 \) case of the theorem corresponds to (4.2) with \( (\alpha, \beta) \mapsto (\alpha_1, \beta-(n-1)k) \).
Proof. The method of proof is identical to that employed in [28, Theorem 1.1] and we only sketch the details of what are essentially elementary manipulations.

We specialise $X \mapsto c(\lambda)_n$ and $Y \mapsto b(\mu)_m$ in Theorem 2.3 and apply the evaluation symmetry (2.8) to obtain

$$\sum_{\nu} \frac{(a, abq^{n}, abq^{m-1}, \ldots, abq^{m-n})_\nu}{(abq^{n}, abq^{m-1}, \ldots, abq^{m-n})_\nu} \mathcal{P}_{\nu}(c(0)_n) \mathcal{P}_{\nu}(\langle \nu \rangle_m)$$

$$= \left( \prod_{i=1}^{n} \frac{(acq^{\lambda_i} t^{m-n})_\infty}{(c t^{m-n})_\infty} \right) \left( \prod_{i=1}^{m} \frac{(bq^{\lambda_i} t^{m-i})_\infty}{(abq^{m-i})_\infty} \right) \times \sum_{\nu} \frac{(a, acq^{\lambda_1} t^{m-2}, \ldots, acq^{\lambda_n} t^{m-n})_\nu}{(acq^{\lambda_1} t^{m-2}, \ldots, acq^{\lambda_n})_\nu} \mathcal{P}_{\nu}(b(0)_m) \mathcal{P}_{\nu}(\langle \nu \rangle_m).$$

Next we replace $t \mapsto q^k$ with $k$ a positive integer and replace $a \mapsto q^3$, $b \mapsto q^{2\nu}$ and $c \mapsto q^{\alpha_1}$. Then we apply [28, Lemma 3.1] to write the $\nu$-sums as $n$-fold unrestricted sums, and the claim follows.

The above derivation can be repeated starting from Theorem 1.2. The result is an $s_1$ variant of the $q$-integral (4.2). Problem with the theorem below is, however, that it does not converge in the $q \to 1^-$ limit unless $m$ or $n$ is 0. (This can be remedied by replacing $[0, 1]^{m+n}$ by appropriate multiple Pochhammer double loops).

**Theorem 4.2.** Let $\lambda = (\lambda_1, \ldots, \lambda_n)$, $\mu = (\mu_1, \ldots, \mu_m)$ be partitions, $k$ a nonnegative integer and $\alpha_1, \alpha_2, \beta_1, \beta_2 \in \mathbb{C}$ such that $\beta_1 + \beta_2 = k + 1$. Then

$$\int_{[0, 1]^{n+m}} \mathcal{P}_{\lambda}(X; q, q^k) \prod_{i=1}^{n} q^{\alpha_1 i} (q x_i)_{\beta_1-1} \prod_{1 \leq i < j \leq n} x_j^{2k} (q^{1-k} x_i/x_j)_{2k}$$

$$\times \mathcal{P}_{\mu}(Y; q, q^k) \prod_{i=1}^{m} y_i^{\alpha_2} (q y_i)_{\beta_2-1} \prod_{1 \leq i < j \leq m} y_j^{2k} (q^{1-k} y_i/y_j)_{2k}$$

$$\times \prod_{i=1}^{n} \prod_{j=1}^{m} y_j^{-k} (q^{1-k} x_i/y_j)^{-k} \, dq X \, dq Y$$

$$= q^{\alpha_1 \binom{n}{2} + \alpha_2 \binom{m}{2} + 2k^2 \binom{n}{2} - k^2 n \binom{n}{2}}$$

$$\times \prod_{i=1}^{n} \Gamma_q(\alpha_1 + (n-i)k + \lambda_i) \Gamma_q(\beta_1 + (i-m+1)k) \Gamma_q(ik+1)$$

$$\times \prod_{i=1}^{m} \Gamma_q(\alpha_2 + (m-i)k + \mu_i) \Gamma_q(\beta_2 + (i-1)k) \Gamma_q(ik+1)$$

$$\times \prod_{i=1}^{n} \prod_{j=1}^{m} \Gamma_q(\alpha_1 + \alpha_2 + (n+m-i-j)k + \lambda_i + \mu_j)$$

for $\text{Re}(\alpha_1) > -\lambda_n$, for $\text{Re}(\alpha_2) > -\mu_m$, and $\beta_1, \beta_2 \neq 0, -1, -2, \ldots$.

**Acknowledgements.** I thank Eric Rains for helpful discussions.
