## Definition of a SFM

Let  $\{(\varphi(t), X(t)), t \ge 0\}$  be a process such that:

- {φ(t), t ≥ 0} is an irreducible CTMC with a (finite) set of phases S and generator T
- $\{\varphi(t), t \ge 0\}$  is the driving process
- Level X(t) records some performance measure
- When  $\varphi(t) = i$ , the rate at which X(t) is changing is  $c_i$

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ - つへつ

### SFM with boundaries 0 and B

・ロン ・四 と ・ ヨ と ・ ヨ

## Definition of a bounded SFM

Let  $\{(\varphi(t), X(t)), t \ge 0\}$  be a process such that:

 {φ(t), t ≥ 0} is an irreducible CTMC with a (finite) set of phases S and generator T

When  $\varphi(t) = i$  then

- $X(t) = 0, c_i < 0 \Longrightarrow dX(t)/dt = 0$
- $X(t) = B, c_i > 0 \Longrightarrow dX(t)/dt = 0$
- Otherwise,  $dX(t)/dt = c_i$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ● ● ○ ○ ○

## Some Notation

• 
$$\mathcal{S}_1 = \{i \in \mathcal{S} : c_i > 0\}$$

• 
$$S_2 = \{i \in S : c_i < 0\}$$

• 
$$\mathcal{S}_0 = \{i \in \mathcal{S} : c_i = 0\}$$

• 
$$\mathbf{C}_1 = diag(c_i)$$
 for all  $i \in S_1$ 

• 
$$C_2 = diag(|c_i|)$$
 for all  $i \in S_2$ 

• 
$$\mathbf{T}_{11} = [\mathbf{T}_{ij}]$$
 for all  $i \in S_1, j \in S_1$ 

• 
$$\mathbf{T}_{12} = [\mathbf{T}_{ij}]$$
 for all  $i \in \mathcal{S}_1, j \in \mathcal{S}_2$ 

• 
$$\mathbf{T}_{10} = [\mathbf{T}_{ij}]$$
 for all  $i \in S_1, j \in S_0$ 

#### etc

## Fluid generator Q(s) (Bean, O'Reilly, and Taylor 2005)

Assume  $Re(s) \ge 0$ 

$$\begin{aligned} \mathbf{Q}_{11}(s) &= \mathbf{C}_{1}^{-1}[(\mathbf{T}_{11} - s\mathbf{I}) - \mathbf{T}_{10}(\mathbf{T}_{00} - s\mathbf{I})^{-1}\mathbf{T}_{01}] \\ \mathbf{Q}_{22}(s) &= \mathbf{C}_{2}^{-1}[(\mathbf{T}_{22} - s\mathbf{I}) - \mathbf{T}_{20}(\mathbf{T}_{00} - s\mathbf{I})^{-1}\mathbf{T}_{02}] \\ \mathbf{Q}_{12}(s) &= \mathbf{C}_{1}^{-1}[\mathbf{T}_{12} - \mathbf{T}_{10}(\mathbf{T}_{00} - s\mathbf{I})^{-1}\mathbf{T}_{02}] \\ \mathbf{Q}_{21}(s) &= \mathbf{C}_{2}^{-1}[\mathbf{T}_{21} - \mathbf{T}_{20}(\mathbf{T}_{00} - s\mathbf{I})^{-1}\mathbf{T}_{01}] \end{aligned}$$

#### Definition

$$egin{aligned} \mathbf{Q}(s) &= \left[ egin{aligned} \mathbf{Q}_{11}(s) & \mathbf{Q}_{12}(s) \ \mathbf{Q}_{21}(s) & \mathbf{Q}_{22}(s) \end{array} 
ight] \ \mathbf{Q} &= \mathbf{Q}(0) \end{aligned}$$

#### In-Out Fluid

Figure: Start in (*i*, 0), end in (*j*, *y*) at time  $\hat{\theta}(y)$ 

12/57

э

## Corresponding Laplace-Stieltjes Transform (LST)

• 
$$|Y(t)| = \int_{u=0}^{t} |c_{\varphi(u)}| du$$
  
•  $\hat{\theta}(y) = \inf\{t \ge 0 : |Y(t)| = y\}$ 

#### Definition

Let 
$$\hat{\Delta}^{y}(s) = [\hat{\Delta}^{y}(s)_{ij}]$$
 be such that for all  $i, j \in S_1 \cup S_2$ 

$$\hat{\Delta}^{\boldsymbol{y}}(\boldsymbol{s})_{ij} = \boldsymbol{E}(\boldsymbol{e}^{-\boldsymbol{s}\hat{\theta}(\boldsymbol{y})}:\varphi(\hat{\theta}(\boldsymbol{y})) = \boldsymbol{j}|\varphi(\boldsymbol{0}) = \boldsymbol{i}, \boldsymbol{Y}(\boldsymbol{t}) = \boldsymbol{0})$$

#### Fact

$$\hat{\Delta}^{y}(s) = e^{\mathbf{Q}(s)y}$$

#### **Return to Level Zero**

Figure: Start in (i, 0), end in (j, 0) at time  $\theta(0)$ 

14/57

# Matrix $\Psi(s)$ (Bean, O'Reilly, and Taylor 2005)

Let  $\theta(0) = \inf\{t \ge 0 : X(t) = 0\}$ 

#### Definition

For *s* with  $Re(s) \ge 0$ , *i* with  $c_i > 0$ , *j* with  $c_j < 0$ , let

$$\Psi(s)_{ij} = E( heta(0) < \infty, heta(0) = i | \varphi(0) = i, X(0) = 0)$$

#### Fact

For  $s \ge 0$ ,  $\Psi(s)$  is the minimum nonnegative solution of

 $\mathbf{Q}_{12}(s) + \mathbf{Q}_{11}(s) \Psi(s) + \Psi(s) \mathbf{Q}_{22}(s) + \Psi(s) \mathbf{Q}_{21}(s) \Psi(s) = \mathbf{0}$

### Remark

Using

- the above building blocks (Q(s),  $\Psi(s)$ ,  $\hat{G}^{x,y}(s)$  and  $\hat{H}^{x,y}(s)$ ),
- and arguments based on appropriate partitioning of sample paths,

the (transient and stationary) analysis of (different classes of) SFMs follows.

We use these building blocks in the analysis of the multi-stage SFMs with congestion control, which is discussed below.

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

## Two-stage SFM (with lower boundary 0)

- Thresholds  $b_1$ ,  $b_2$ ,  $0 < b_1 < b_2$ , for controlling congestion.
- The process starts from Stage 1 in level 0
- Stage 1  $\rightarrow$  Stage 2 when reaching  $b_2$  from below
- Stage 2  $\rightarrow$  Stage 1 when reaching  $b_1$  from above
- Matrices P<sup>(b<sub>2</sub>)</sup>, P<sup>(b<sub>1</sub>)</sup> record the probabilities of these transitions

While in Stage  $\ell \in \{1, 2\}$ ,

the process evolves according to a traditional SFM with a set of phases S<sup>ℓ</sup>, generator T<sup>ℓ</sup> and fluid rates c<sup>ℓ</sup><sub>i</sub>

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

## Mutli-stage SFMs

This class of models contains a model introduced by Malhotra, Mandjes, Scheinhardt and van den Berg (2009).

- Any real fluid change rates  $c_i^{(\ell)}$  (including zero), where  $i \in S^{(\ell)}$ , and  $\ell = 1, 2$  is the current stage.
- The transition between the stages may involve not only the change in T<sup>(l)</sup>, but also in S<sup>(l)</sup>.
- The change in c<sub>i</sub><sup>(ℓ)</sup> at the moment of the transition between the stages allows all possible types of changes of sign (from + or − to +, − or 0).
- We treat the model with an *upper boundary*  $B > b_2$ .
- We consider a generalization to *multi-stage* SFMs.

# Mutli-stage SFMs

Methodology:

• The analysis in Malhotra, Mandjes, Scheinhardt and van den Berg (2003) was based on solving appropriate balance equations using a spectral expansion.

• Here, we use the building blocks discussed earlier, and matrix-analytic methods.

Model with no upper boundary is discussed below. The analysis for the bounded model is similar.

## Stationary Analysis: Existence

The stationary distribution of the two-stage SFM exists when the drift

$$\mu^{(2)} = \sum_{i \in \mathcal{S}^{(2)}} \pi_i \boldsymbol{c}_i^{(2)},$$

corresponding to the SFM in Stage 2, is strictly negative.

イロト 不得 とくほと くほとう

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

# Stationary Analysis: Steps of the Method

1. Derive the stationary distribution vector  $\boldsymbol{\xi} = \begin{bmatrix} \boldsymbol{\xi}^{(0)} & \boldsymbol{\xi}^{(b_1)} & \boldsymbol{\xi}^{(b_2)} \end{bmatrix}$  of a DTMC observed at the moments when hitting level 0 (from above), or  $b_1$  from above while in Stage 2, or  $b_2$  from below

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

# Stationary Analysis: Steps of the Method

The one-step transition probability matrix **A** of this chain, partitioned in an analogous manner, is given by

$$\mathbf{A} = \left[egin{array}{cccc} \mathbf{A}_{00} & \mathbf{0} & \mathbf{A}_{0b_2} \ \mathbf{A}_{b_10} & \mathbf{0} & \mathbf{A}_{b_1b_2} \ \mathbf{0} & \mathbf{A}_{b_2b_1} & \mathbf{0} \end{array}
ight]$$

where

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

## Stationary Analysis: Steps of the Method

2. Write expressions for the probability mass vectors  $[\mathbf{p}(0)_2 \ \mathbf{p}(0)_0], \mathbf{p}(b_2)_0$ , and  $\mathbf{p}(b_1)_0$ , in terms of  $\boldsymbol{\xi}$  and some normalizing constant  $\alpha$ 

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

## Stationary Analysis: Steps of the Method

We have

$$\begin{bmatrix} \mathbf{p}(0)_2 & \mathbf{p}(0)_0 \end{bmatrix} = \alpha \begin{bmatrix} \boldsymbol{\xi}^{(0)} & \mathbf{0} \end{bmatrix} \begin{pmatrix} -\begin{bmatrix} \mathbf{T}_{22}^{(1)} & \mathbf{T}_{20}^{(1)} \\ \mathbf{T}_{02}^{(1)} & \mathbf{T}_{00}^{(1)} \end{bmatrix} \end{pmatrix}^{-1}$$
$$\mathbf{p}(b_2)_0 = \alpha \boldsymbol{\xi}^{(b_2)} \mathbf{P}_{10}^{(b_2)} (-\mathbf{T}_{00}^{(2)})^{-1}$$
$$\mathbf{p}(b_1)_0 = \alpha \boldsymbol{\xi}^{(b_1)} \mathbf{P}_{20}^{(b_1)} (-\mathbf{T}_{00}^{(1)})^{-1}$$

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

### Long-run proportion of time spent in a stage

Using the above results, we can evaluate

$$p^{(1)} = \int_{x=0}^{b_2} \pi^{(1)}(x) dx \mathbf{1} + \mathbf{p}(0) \mathbf{1} + \mathbf{p}(b_1) \mathbf{1},$$
  

$$p^{(2)} = \int_{x=b_1}^{\infty} \pi^{(2)}(x) dx \mathbf{1} + \mathbf{p}(b_2) \mathbf{1},$$

interpreted as the long-run proportion of time spent in Stage 1 and Stage 2, respectively.

### Transient tendency of the switches

between the two stages can be assessed using

$$\begin{split} \delta_{2 \to 1} &= \frac{1}{(\mathbf{1}/|\mathcal{S}_1^{(1)}|) \mathbf{E}_{b_2 b_1} \mathbf{1}}, \\ \delta_{1 \to 2} &= \frac{1}{(\mathbf{1}/|\mathcal{S}_2^{(2)}|) \tilde{\mathbf{E}}_{b_1 b_2} \mathbf{1}}, \end{split}$$

with  $\delta_{2\to1}$  and  $\delta_{1\to2}$  interpreted as the transient rate of the switch from Stage 2 to 1 and from Stage 1 to 2, respectively, and where a higher rate means a faster switch to the other stage.

Two-stage SFMs Transient Analysis Stationary Analysis Additional measures Multi-stage SFMs

Stationary tendency of the switches

between the two stages can be assessed using

$$\begin{split} r_{2 \to 1} &= \frac{1}{\pi^{(1)} (b_2^-)_1 \mathbf{E}_{b_2 b_1} \mathbf{1}}, \\ r_{1 \to 2} &= \frac{1}{\pi^{(1)} (b_1^+)_2 \tilde{\mathbf{E}}_{b_1 b_2} \mathbf{1}}, \end{split}$$

with  $r_{2\rightarrow 1}$  and  $r_{1\rightarrow 2}$  interpreted as the long-run rate of the switch from Stage 2 to 1 and from Stage 1 to 2, respectively, and where a higher rate means a faster switch to the other stage.

## Multi-stage SFMs

• Thresholds  $u_k$ ,  $d_k$ ,  $k = 2, \ldots, n$ , with

$$0 < d_k < u_k < d_{k+1}$$

- Hitting u<sub>k</sub> from below while in Stage (k − 1) results in Stage (k − 1) → Stage k
- Hitting *d<sub>k</sub>* from above while in Stage *k* results in Stage *k* → Stage (*k* − 1)

The analysis is built upon arguments similar to before, and is more complex.

Related models (with  $d_k = u_k$ ): Bean and O'Reilly (2008), Da Silva Soares and Latouche (2009)
